HELL YES! CSS!

by Julia Evans

♡ this?

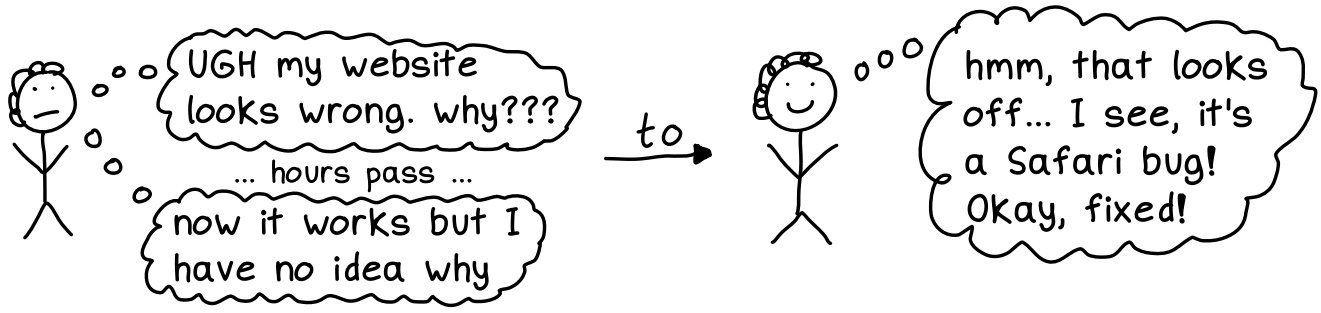
★ wizardzines.com ★

what's this?

I wrote this zine because, after 15 years of being confused about CSS, I realized I was still missing a lot of basic CSS knowledge. Learning the facts in this zine helped me go from:



This zine also comes with ;examples; for you to try out. They're at:

https://css-examples.wizardzines.com

Panels which have examples you can try are labelled TRY ME!

thanks for reading

CSS is a HUGE topic and there's a lot more to learn than what's in this zine. Here are some of my favourite CSS resources:

♡CSS Tricks (css-tricks.com)

Hundreds of helpful blog posts and incredible guides, like their guides to centering & flexbox.

♡Mozilla Developer Network (developer.mozilla.org)

My favourite reference for CSS, JS, HTML, and HTTP

♡Can I use... (caniuse.com)

Tells you which browser versions (and what likely % of your users) have support for each CSS feature.

♡W3 (w3.org/TR/CSS)

The CSS specifications. Can be useful as a reference too!

and thanks to all the beta readers ♡

testing checklist

Finally, it's important to test your site with different browsers, screen sizes, and accessibility evaluation tools.

browsers

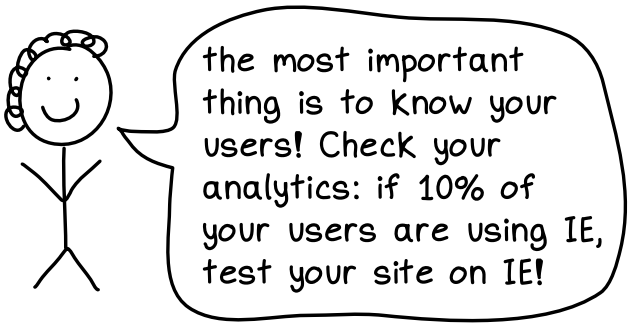
- ☐ Chrome
- ☐ Safari
- ☐ Firefox
- ☐ maybe others!

sizes

- ☐ small phone (300px wide)
- ☐ tablet (~700px)
- ☐ desktop (~1200px)

accessibility

- ☐ colour contrast
- ☐ text size
- ☐ keyboard navigation
- ☐ works with a screen reader



performance

- ☐ fake a slow/high latency network connection!

table of contents

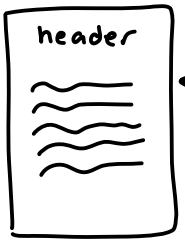
CSS isn't easy

CSS seems simple at first

```
h2 {
  font-size: 22px;
}
```

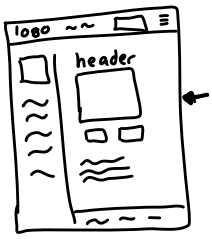
ok this is easy!

and it is easy for simple tasks



a layout like this is simple to implement!

but website layout is not an easy problem



this needs to adjust to so many screen sizes!

the spec can be surprising

TRY ME!

setting `overflow: hidden;` on an inline-block element changes its vertical alignment

CSS 2.1

weird!

and all browsers have bugs

I don't support flexbox for <summary> elements

safari

ok fine

accept that writing CSS is gonna take time

if I'm patient I can fix all the edge cases in my CSS and make my site look great everywhere!

the CSS inspector

all major browsers have a CSS inspector

usually you can get to it by right clicking on an element and then "inspect element, but sometimes there are extra steps

see overridden properties

```
button {
  display: inline-block;
  color: var(--orange);
}
```

edit CSS properties

```
element {
}
```

lets you change this element's properties

```
button {
  display: inline-block;
  border: 1px solid black;
}
```

this lets you change the border of every <button>!

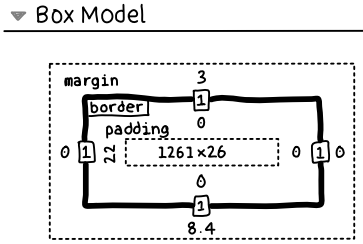
see computed styles

here's a website with 12000 lines of CSS, what `font-size` does this link have?

12px, because of x.css line 436

browser

look at margin & padding



... and LOTS more

different browsers have different tools! For example, Firefox has special tools for debugging grid/flexbox

media queries

media queries let you use different CSS in different situations

```
@media print {
  #footer {
    display: none;
  }
}
```

media query

CSS to apply

max-width & min-width

```
@media (max-width: 500px) {
   // CSS for small screens
}

@media (min-width: 950px) {
   // CSS for large screens
}
```

print and screen

`screen` is for computer/ mobile screens

`print` is used when printing a webpage

there are more: `tv`, `tty`, `speech`, `braille`, etc

accessibility queries

you can sometimes find out a user's preferences with media queries

examples:

```
prefers-reduced-motion: reduce
prefers-color-scheme: dark
```

you can combine media queries

it's very common to write something like this:

```
@media screen and
    (max-width: 1024px)
```

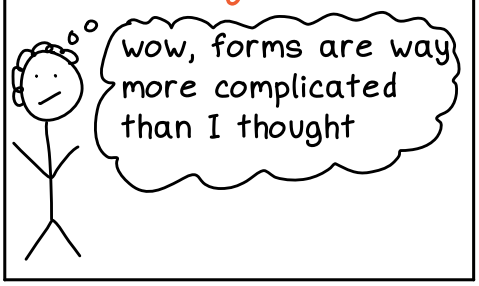
the viewport meta tag

```
<meta name="viewport"
content="width=device-width,
initial-scale=1">
```

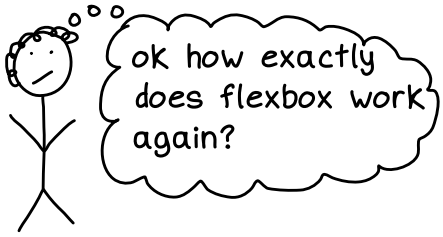
Your site will look bad on mobile if you don't add a tag like this to the `<head>` in your HTML. Look it up to learn more!

CSS != design

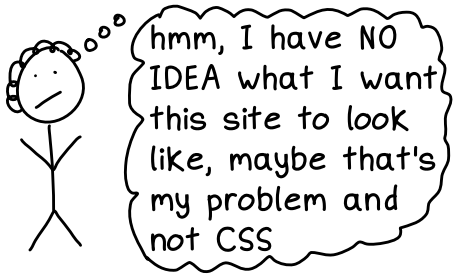
web design is really hard



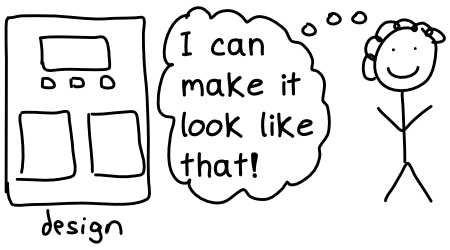
writing CSS is also hard



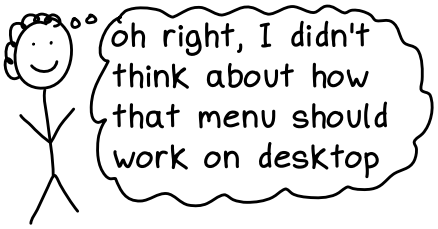
remember that they're 2 different skills



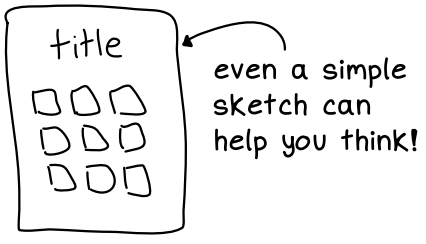
CSS is easier when you have a good design



usually you have to adjust the design



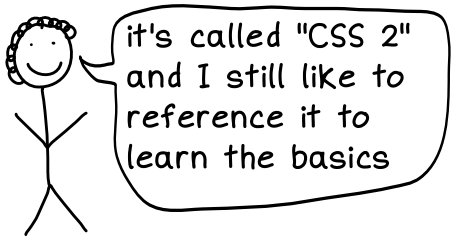
sketching a design in advance can help!



CSS specifications

CSS has specifications

there used to be just one specification



today, every CSS feature has its own specification

you can find them all at `https://www.w3.org/TR/CSS/`

there are dozens of specs, for example: colors, flexbox, and transforms

major browsers usually obey the spec

but sometimes they have bugs

levels

CSS versions are called "levels".

new levels only add new features. They don't change the behaviour of existing CSS code

new features take time to implement

`https://caniuse.com` can tell you which browser versions support a CSS feature

transitions

an element's computed style can change

2 ways this can happen:

1. pseudo-classes (like `:hover`)
2. Javascript code `el.classList.add('x')`

new styles change the element instantly...

```
a:hover {
  color: red;
}
```

the element will turn red right away

... unless you set the `transition` property

TRY ME!

```
a {
  color: blue;
  transition: all 2s;
}
a:hover {
  color: red;
}
```

will fade from blue to red over 2s

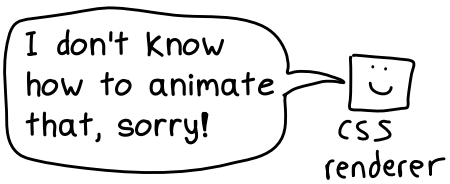
`transition` has 3 parts

```
transition: color 1s ease;
```

which CSS properties to animate — duration — timing function

not all property changes can be animated....

```
list-style-type: square;
```



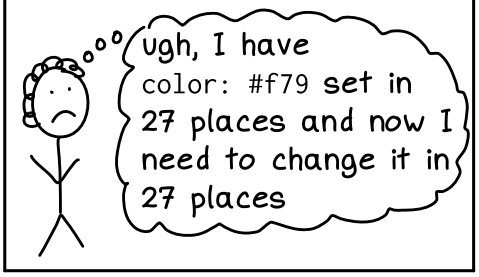
...but there are dozens of properties that can

if it's a number or color, it can probably be animated!

```
font-size: 14px;
rotate: 90deg;
width: 20em;
```

CSS variables

duplication is annoying



define variables in any selector

```
body {
  --text-color: #f79;
}
#header {
  --text-color: #c50;
}
```

applies to everything

applies to children of #header

use variables with var()

```
body {
   color: var(--text-color);
}
```

variables always start with --

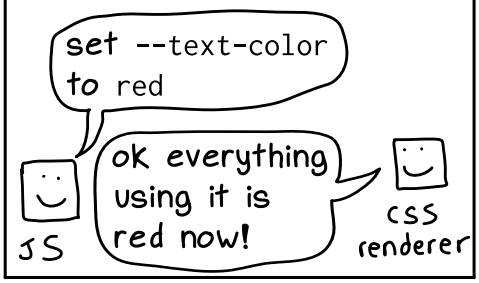
do math on them with calc()

```
#sidebar {
   width: calc(
       var(--my-var) + 1em
   );
}
```

you can change a variable's value in Javascript

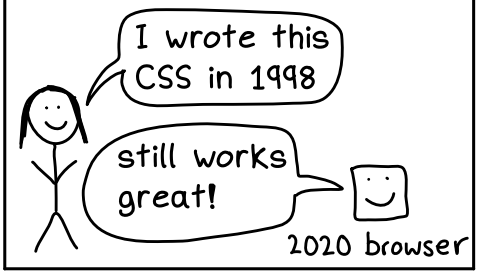
```
let root =
  document.documentElement;
root.style.setProperty(
   '--text-color', 'black');
```

changes to variables apply immediately



backwards compatibility

browsers support old HTML + CSS forever



this makes CSS hard to write...

... but it means it's worth the investment

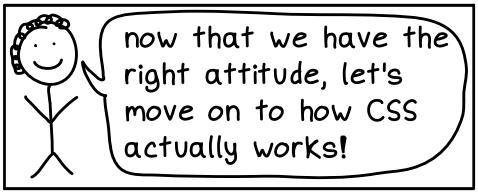
if you don't follow the standards, you're not guaranteed backwards compatibility

your CSS doesn't have to support browsers from 1998

newer features are often easier to use

what people expect from a website has changed a LOT since 1998. Newer CSS features make responsive design easy

a few CSS selectors



div

matches `div` elements

```
<div>
```

#welcome

`#` matches elements by `id`

```
<div id="welcome">
```

.button

`.` matches elements by `class`

```
<a class="button">
```

div .button

match every `.button` element that's a descendent of a `div`

div.button

match divs with class "button"

```
<div class="button">
```

div > .button

match every `.button` element that's a direct child of a `div`

.button, #welcome

matches both `.button` and `#welcome` elements

[href^="http"]

match `a` elements with a `href` attribute starting with `http`

:checked

matches if a checkbox or radio button is checked

a:hover

matches `a` elements that the cursor is hovering over

tr:nth-child(odd)

match alternating `tr` elements (make a striped table!)

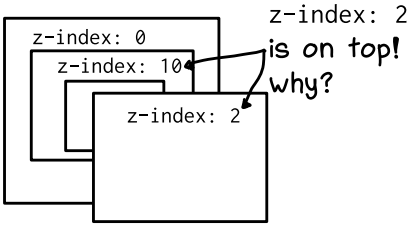
stacking contexts

a z-index can push an element up/down...

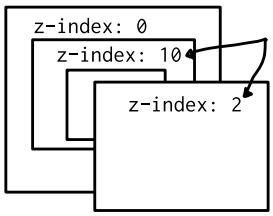
```
.first {
  z-index: 3;
}
.second {
  z-index: 0;
}
```

... but a higher z-index doesn't always put an element on top

TRY ME!

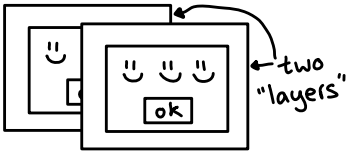


every element is in a stacking context



these 2 elements are in different stacking contexts

a stacking context is like a Photoshop layer



by default, an element's children share its stacking context

setting z-index creates a stacking context

```
#modal {
    z-index: 5;
    position: absolute;
}
```

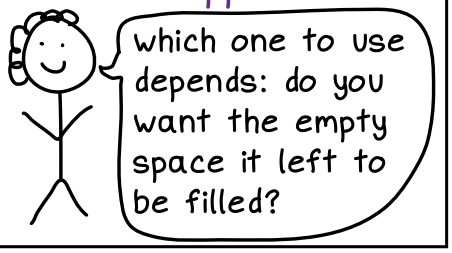
this is a common way to create a stacking context

stacking contexts are confusing

You can do a lot without understanding them at all. But if `z-index` ever isn't working the way you expect, that's the day to learn about stacking contexts :)

hiding elements

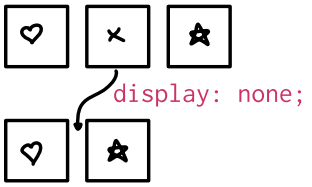
there are many ways to make an element disappear



display: none;

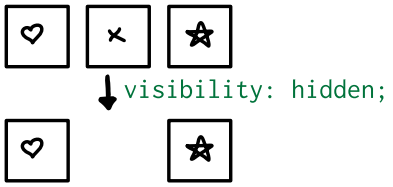
TRY ME!

other elements will move to fill the empty space



visibility: hidden;

the empty space will stay empty



opacity: 0;

like `visibility: hidden`, but you can still click on the element & it'll still be visible to screen readers. Usually `visibility: hidden` is better.

how to slowly fade out

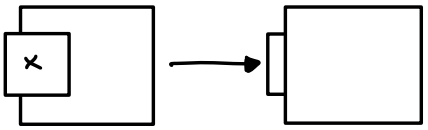
```
#fade:hover {
  transition: all 1s ease;
  visibility: hidden;
  opacity: 0;
}
```

set the opacity just so that the transition works

z-index

TRY ME!

z-index sets the order of overlapping positioned elements



specificity

different rules can set the same property

```
a:visited {
  color: purple;
  font-size: 1.2em;
}
#start-link {
  color: orange;
}
```

which one gets chosen?

CSS uses the "most specific" selector that matches an element

In our example, the browser will use `color: orange` because IDs (like `#start-link`) are more specific than pseudoclasses (like `:visited`)

CSS can mix properties from different rules

TRY ME!

```
a:visited {
  color: purple;
  font-size: 1.2em;
}
#start-link {
  color: orange;
}
```

it'll use this font-size

but use this color because #start-link is more specific

how CSS picks the "most specific" rule

a selector with element names
```
body div span a {
    color: red;
}
```

loses to

a selector with .classes or :pseudoclasses
```
.sidebar .link {
    color: orange;
}
```

loses to

a selector with an #id
```
#header a {
    color: purple;
}
```

loses to

an inline style
`style="color: green;"`

loses to

an `!important` rule*
`color: blue !important;`

`!important` is very hard to override, which makes life hard for your future self!

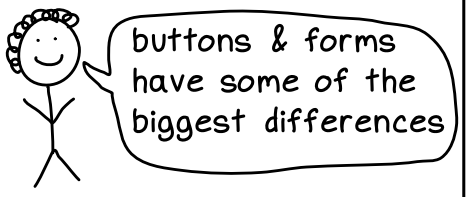
default stylesheets

every browser has a default stylesheet
(aka "user agent stylesheet")

a small sample from the Firefox default stylesheet:

```
h1 {
  font-size: 2em;
  font-weight: bold;
}
```

different browsers have different defaults



you can read the default stylesheet

Firefox's default stylesheets are at:

`resource://gre-resources/`

every property also has a default "initial value"

the initial value (defined in the spec) is what's used if no stylesheet has set anything. For example, `background-color`'s initial value is `transparent`

a CSS property can be set in 5 ways

lowest priority

1. the initial value
2. the browser's default stylesheet
3. the website's stylesheets
4. a user stylesheet (least common)
5. inline styles set with HTML/JS

highest priority

position: absolute

`position: absolute;` doesn't mean absolutely positioned on the page: it's relative to the "containing block"

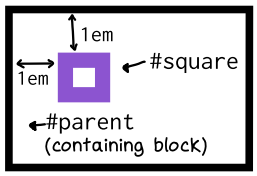
TRY ME!

the "containing block" is the closest ancestor with a `position` that isn't set to `static` (the default value), or the body if there's no such ancestor.

Here's some typical CSS:

```
#square {
  position: absolute;
  top: 1em; left: 1em;
}
#parent {
  position: relative;
}
```

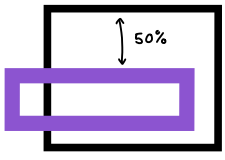
this makes #parent the containing block



`top`, `bottom`, `left`, `right` will place an absolutely positioned element

```
top: 50%;
bottom: 2em;
right: 30px;
left: -3em;
```

negative works too



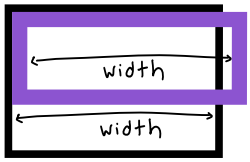
`left: 0; right: 0;` ≠ `width: 100%;`

TRY ME!

`left: 0; right: 0;`

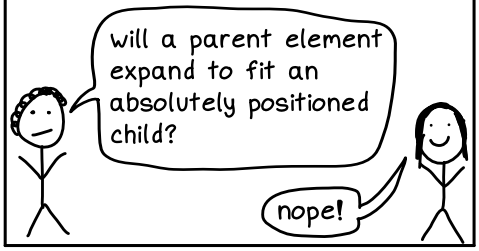
left and right borders are both 0px away from containing block

`width: 100%;`



the box sticks out because `width` doesn't include borders by default

absolutely positioned elements are taken out of the normal flow



centering

center text with text-align

```
h2 {
  text-align: center;
}
```

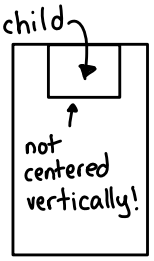
center block elements with margin: auto

example HTML:

```
<div class="parent">
  <div class="child">
  </div>
</div>
```

margin: auto only centers horizontally

```
.child {
  width: 400px;
  margin: auto;
}
```



vertical centering is easy with flexbox or grid

TRY ME!

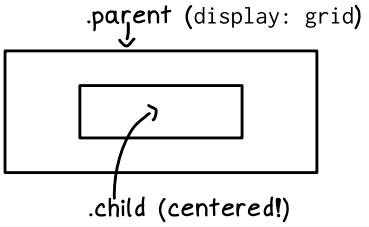
here's how with grid:

```
.parent {
  display: grid;
  place-items: center;
}
```

and with flexbox:

```
.parent {
  display: flex;
}
.child {
  margin: auto;
}
```

it's ok to use a flexbox or grid just to center one thing



units

CSS has 2 kinds of units: absolute & relative

absolute: `px`, `pt`, `pc`, `in`, `cm`, `mm`

relative: `em`, `rem`, `vw`, `vh`, `%`

rem

the root element's font size

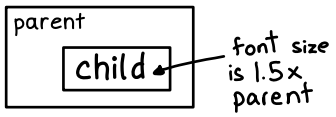
`1rem` is the same everywhere in the document. `rem` is a good unit for setting font sizes!

em

TRY ME!

the parent element's font size

```
.child {
  font-size: 1.5em;
}
```



0 is the same in all units

```
.btn {
  margin: 0;
}
```

also, `0` is different from `none`. `border: 0` sets the border width and `border: none` sets the style

1 inch = 96 px

on a screen, 1 CSS "inch" isn't really an inch, and 1 CSS "pixel" isn't really a screen pixel. look up "device pixel ratio" for more.

rem & em help with accessibility

```
.modal {
  width: 20rem;
}
```

this scales nicely if the user increases their browser's default font size

inline vs block

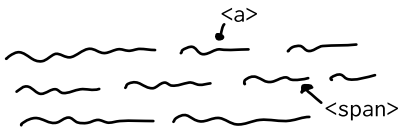
HTML elements default to inline or block

example inline elements:
<a>
 <i>
<small> <abbr>
<img> <q>
<code>

example block elements:
<p>

<h1> - <h6>
<blockquote>
<pre>

inline elements are laid out horizontally



block elements are laid out vertically by default

to get a different layout, use `display: flex` or `display: grid`

inline elements ignore `width` & `height`*

Setting the width is impossible, but in some situations, you can use `line-height` to change the height

*`img` is an exception to this: look up "replaced elements" for more

`display` can force an element to be inline or block

`display` determines 2 things:

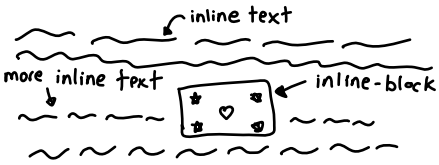
① whether the element itself is `inline`, `block`, `inline-block`, etc

② how child elements are laid out (`grid`, `flex`, `table`, default, etc)

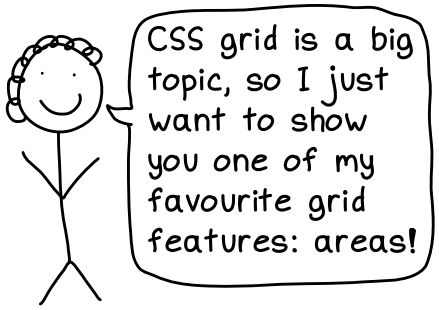
`display: inline-block;`

TRY ME!

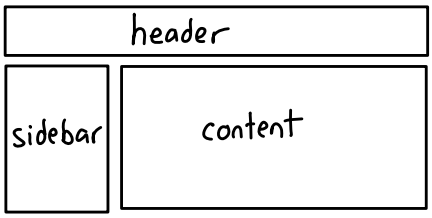
`inline-block` makes a block element be laid out horizontally like an inline element



CSS grid: areas!



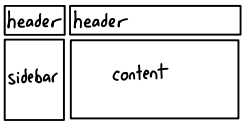
let's say you want to build a layout



`grid-template-areas` lets you define your layout in an almost visual way

```
grid-template-areas:
  "header header"
  "sidebar content";
```

I think of it like this:



1. write your HTML

TRY ME!

```
<div class="grid">
  <div class="top"></div>
  <div class="side"></div>
  <div class="main"></div>
</div>
```

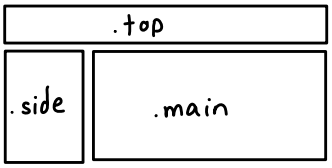
2. define the areas

```
.grid {
  display: grid;
  grid-template-columns:
      200px 800px;
  grid-template-areas:
    "header header"
    "sidebar content";
}
```

3. set `grid-area`

```
.top {grid-area: header}
.side {grid-area: sidebar}
.main {grid-area: content}
```

result:



flexbox basics

TRY ME!

display: flex;

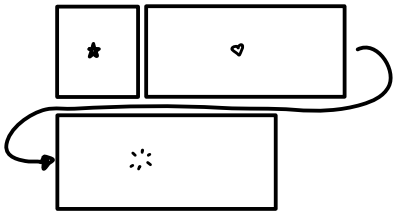
set on a parent element to lay out its children with a flexbox layout.

by default, it sets `flex-direction: row;`

flex-direction: row;

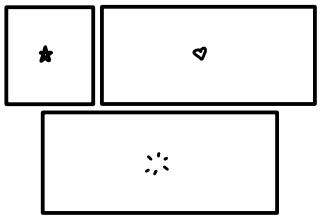
by default, children are laid out in a single row. the other option is `flex-direction: column`

flex-wrap: wrap;



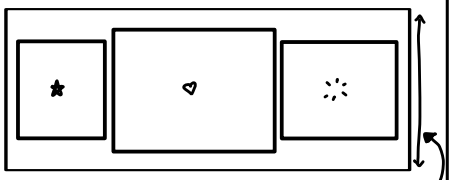
will wrap instead of shrinking everything to fit on one line

justify-content: center;



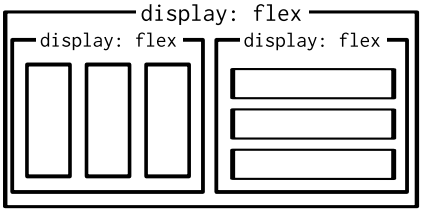
horizontally center (or vertically if you've set `flex-direction: column`)

align-items: center;



vertically center (or horizontally if you've set `flex-direction: column`)

you can nest flexboxes

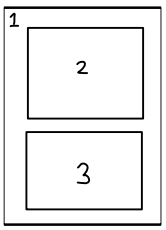


the box model

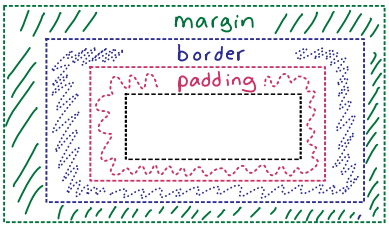
every HTML element is in a box

```
<div class="1">
  <div class="2" />
  <div class="3" />
</div>
```

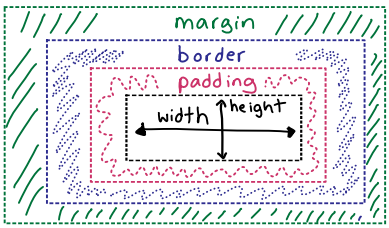
=>



boxes have padding, borders, and a margin

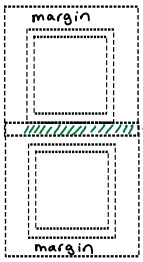


width & height don't include any of those



margins are allowed to overlap sometimes

TRY ME!

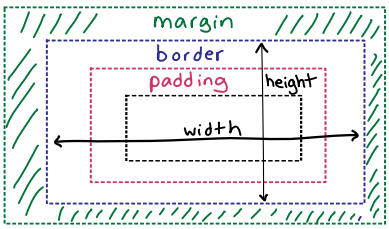


the browser combines these top/bottom margins

look up "margin collapse" to learn more

box-sizing: border-box;

includes border + padding in the width/height



padding & border are inside the element, margin is outside

For example, clicking on an element's border/padding triggers its `onclick` event, but clicking on the margin doesn't.

padding + margin syntax

there are 4 ways to set padding

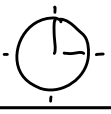
all sides
```
padding: 1em;
```
vertical horizontal
```
padding: 1em 2em;
```
top horizontal bottom
```
padding: 1em 2em 3em;
```
top right bottom left
```
padding: 1em 2em 3em 4em;
```

tricks to remember the order

① trouble

top right bottom left

② it's clockwise



you can also set padding on just 1 side

```
padding-top: 1em;
padding-right: 10px;
padding-bottom: 3em;
padding-left: 4em;
```

differences between padding & margin

TRY ME!

- padding is "inside" an element: the background color covers the padding, you can click padding to click an element, etc. Margin is "outside".
- you can center with `margin: auto`, but not with padding
- margins can be negative, padding can't

margin syntax is the same as padding

`border-width` also uses the same order: top, right, bottom, left

borders

border has 3 components

```
border: 2px solid black;
```

is the same as

```
border-width: 2px;
border-style: solid;
border-color: black;
```

border-style options

solid

dotted

dashed

double

+ lots more (inset, groove, etc)

border-{side}

you can set each side's border separately:

```
border-bottom:
    2px solid black;
```

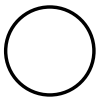
border-radius

border-radius lets you have rounded corners

```
border-radius: 10px;
```

```
border-radius: 50%;
```

will make a square into a circle!



box-shadow

lets you add a shadow to any element

element shadow

color

box-shadow: 5px 5px 8px black;

x offset y offset blur radius

outline

TRY ME!

outline is like border, but it doesn't change an element's size when you add it

element

outlines on :hover/:active help with accessibility: with keyboard navigation, you need an outline to see what's focused
